Teaching Statement

William Duan — Vancouver School of Economics, University of British Columbia

I find teaching deeply rewarding. Introducing students to economics is among the parts of academic work I value most, and I intend for it to remain central to my career. Over seven years as a teaching assistant I have taught economics successfully from first-year principles to the PhD microeconomic theory sequence, which I have supported every year since 2021. In Summer 2026 I designed and taught the School's graduate Math Camp. I can teach effectively at any level of the curriculum, from a first-year audience to the most technically demanding courses.

I would be glad to teach any course in the undergraduate curriculum, including macroeconomics and econometrics. My strongest interest is in microeconomics, from principles through game theory, information economics, and auctions and market design. At the graduate level, I am best prepared to teach mathematics for economists and the microeconomic theory core.

Teaching philosophy

I believe that at university, students lead their own learning. Understanding is something they build through their own work, and no lecture can do that work for them. The instructor's role is to make that work possible, and I see that role as three tasks.

The first is to give students a reason to do the work. Effort that students choose to make depends on seeing why the material matters, so motivation is where teaching starts, not something added later. The second is to set out clearly what students are expected to know and be able to do, and to what level. Students who lead their own learning need to know where they are going, and a clear target lets them judge their progress themselves rather than wait for an exam to judge it. The third is to help them past the points where they get stuck. These are the moments when self-directed learning is most likely to stall, and where an instructor adds the most.

The three tasks depend on one another. Motivation without a clear target produces effort that drifts. A clear target without support leaves students facing the hardest parts alone. Support is only useful once students are invested enough to want it and know enough about the goal to see where they are stuck.

Teaching practice

I carry out these tasks mostly through problems. A tool is easier to motivate when students first see the problem it was built to solve, whether an academic question or a practical one, so I introduce material through questions. We solve them together, with me calling on students as we go. Working a problem also tells students where they stand. A problem they can finish confirms what they understand, and the point where they get stuck shows them, and me, which part of the general idea they have not yet grasped. Handing students the reasoning in this way does not depend on a small room, and the same principle has been applied successfully in large introductory economics courses.[1]

Proofs follow the same principle. Intuition comes first and the technical steps second, because the aim of a proof is not to take students through each step but to give them enough understanding of the result to use it themselves. I present a result in four stages. I begin with what it says and where it applies. I either show what would go wrong without it, so that students see what it gives them, or use a graphical or numerical illustration where one exists. I then explain why the result is not obvious, which identifies the core fact the proof has to establish. Next I go through the intuition of the proof, built on those first two stages. Only then do I turn to

the technical details and the formal argument. The same approach applies to abstract analytical results at any level.

In class I present one clean, linear solution first and save alternative routes for the end. A clean solution shows students how an argument should go, and in the PhD core I also want them to recognize when one does not. For some time I have presented proofs that are correct in their approach but omit a few necessary and subtle steps, and asked students to find where the argument is incomplete. This year I have started generating flawed proofs with weaker AI models for the same exercise. Reading a plausible argument and finding where it fails is among the most valuable skills a graduate student can take from a theory course, and reading correct proofs does not train it.

Finally, helping students past the hard parts depends on knowing where those parts are, and students know far more about what they do not understand than an instructor can observe. So I try to make it easy for students to show me where they are stuck. I work at making students comfortable with me, through a casual manner and an interest in their lives beyond the course, so that they will bring me even their small questions. When they do, I try to reconstruct how they were thinking before I say anything, because the useful answer is the correct solution attached to the place where their reasoning went wrong. In a large class the useful connection is among the students. In my principles of microeconomics sections I put the whole class into one group chat and routed every question through it. Most were answered by classmates before I saw them, and my job became confirming the answer or adding a small correction. Students who would never have emailed a teaching assistant asked freely there.

This question channel is the practice I am most confident will scale to a large lecture course, because I have already run it with sections of up to sixty students. In a large course I would route all questions through one moderated forum, with a small amount of bonus credit for correct answers to classmates.[2] This makes the strongest students a resource for the whole class without assigned groups, which students rarely welcome. Class time would remain devoted to lectures and worked problems. I would keep calling on students as a problem is solved, so that a large room follows the reasoning step by step rather than receiving only the answer.

Evidence of teaching effectiveness

Course	Years	Sections	Responses	Median, /5	Good or very good
ECON 600/601 (PhD micro theory)	2021–2026	10	104	4.8–5.0	100%
ECON 514 (information and incentives)	2021	1	7	4.8	100%
ECON 101 (principles of micro)	2020, 2025	3	34	4.5–4.9	92–100%
ECON 303, 355 (intermediate micro, trade)	2019–2020	2	44	4.5–4.7	70–74%
Total	**2019–2026**	**16**	**189**	**4.5–5.0**	**96% average**

Across the sixteen reports, an average of 96% of responding students rated my overall contribution good or very good. I received the Vancouver School of Economics Agustín Beltrán Award for Excellence in Teaching, the School's award for teaching assistants, in 2024, 2025 and 2026. My teaching dossier gives the full results, sample materials and my other contributions to teaching, and is also online at william96123.github.io/teaching.
